

# Behaviour Trees Representation

→ Root (Sequence Node)

## Keys / Legends

→ (Sequence Node)

↩ (Fallback Node)

◇ (Condition)

□ (Action)

(a) How does the Fallback node help in making better decisions?

Srinath S

Ans: ① A fallback node tries child nodes until one succeeds; i.e. in the sense acts like a priority based decision.

② Ex: Battery check;

↳ Here the more checks critical case first

↳ If above case is false it checks low battery & so on.

③ This ensures efficient handling of edge cases without redundant checks.

(b) Why is it better than using a long if-else condition?

Ans: ① Readability: Flowcharts are easy to comprehend than codes. Provides ease in debugging.

② Flexibility: Nodes can be rearranged/swapped without rewriting the entire logic.

③ Modularity: It breaks logic into reusable nodes.

(c) Handling "Low but not Critically Low" Battery

Ans: • The fallback node evaluates its child until one succeeds. So Process is as follows;

↳ Critically Low? → Fails & moves to next child

↳ Low but not critical → Succeeds & turns off cameras & runs in reduced power usage.
